Performance

CPU Performance

Chap. 1.6, 2.13

Performance Issues

- Measure, analyze, report, and summarize

- Make intelligent choices

- See through the marketing hype

- Key to understanding underlying organizational motivation

- Questions
  - Why is some hardware better than others for different programs?
  - What factors of system performance are hardware related?
    (e.g., Do we need a new machine or a new operating system?)
  - How does the machine's instruction set affect performance?

Understanding Performance

- **Algorithm**
  - Determines number of operations executed

- **Programming language, compiler, architecture**
  - Determine number of machine instructions executed per operation

- **Processor and memory system (microarchitecture)**
  - Determine how fast instructions are executed

- **I/O system (including OS)**
  - Determines how fast I/O operations are executed

Defining Performance

- Which airplane has the best performance?
Performance Metric

- **Response time (≈ execution time, latency)**
  - The time between the start and completion of a task
  - How long does it take for my job to run?
  - How long must I wait for the database query?

- **Throughput (≈ bandwidth)**
  - The total amount of work done in a given time
  - How much work is getting done per unit time?
  - What is the average execution rate?

- **What if …**
  - We replace the processor with a faster version?
  - We add more processors?

Relative Performance

- Define

$$Performance = 1/Execution\ Time$$

- "X is n times faster than Y"

$$\frac{Performance_X}{Performance_Y} = \frac{Execution\ time_Y}{Execution\ time_X} = n$$

- Example: time taken to run a program
  - 10s on machine A, 15s on machine B
  - Execution Time$_B$ / Execution Time$_A$ = 15s / 10s = 1.5
  - Machine A is 1.5 times faster than machine B

Measuring Execution Time

- **Elapsed time**
  - Total response time, including all aspects
    - e.g., processing, I/O, OS overhead, idle time
  - Determines system performance

- **CPU time**
  - Time spent processing a given job
    - Discounts I/O time, other jobs' shares
  - Comprises user CPU time and system CPU time
  - Different programs are affected differently by CPU and system performance

- **Our focus: User CPU time**

CPU Clocking

- Operation of digital hardware governed by a constant-rate clock
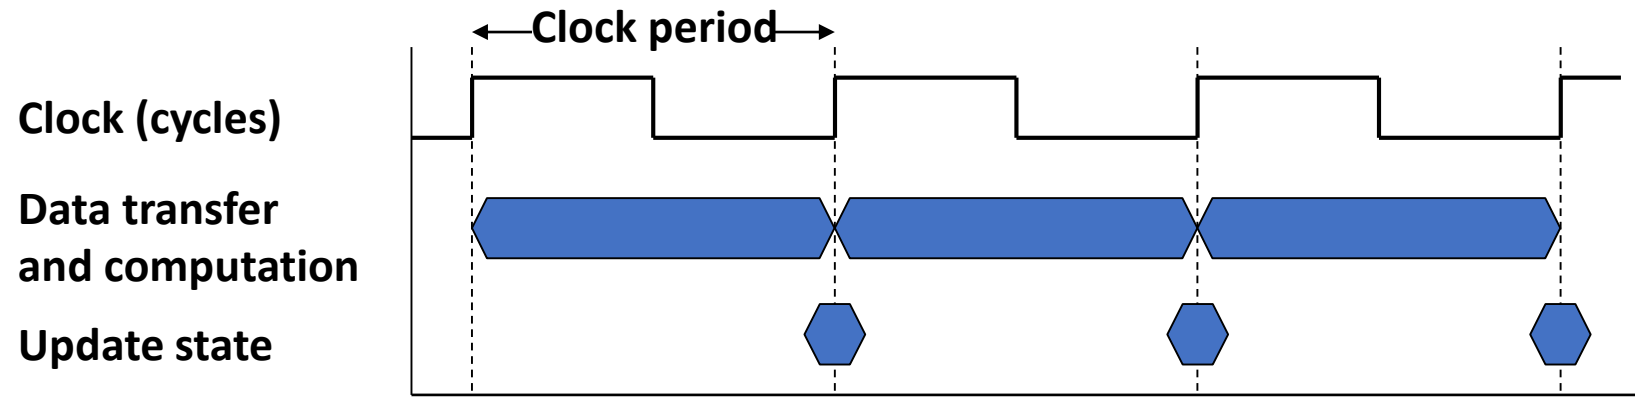

- Clock period: duration of a clock cycle
  - e.g., 250ps = 0.25ns = 250×10^{-12} s
- Clock frequency (rate): cycles per second
  - e.g., 4.0GHz = 4000MHz = 4.0×10^9 Hz

CPU Time

$$CPU\ Time\ =\ CPU\ Clock\ Cycles \times Clock\ Cycle\ Time$$

$$=\ \frac{CPU\ Clock\ Cycles}{Clock\ Rate}$$

- **Performance improved by**
  - Reducing number of clock cycles
  - Increasing clock rate (or decreasing the clock cycle time)
  - Hardware designer must often trade off clock rate against cycle count

CPU Time Example

- Computer A: 2GHz clock, 10s CPU time

- Designing Computer B
  - Aim for 6s CPU time
  - Can do faster clock, but causes 1.2 x clock cycles

- How fast must Computer B's clock be?

$$Clock\ Cycles_A = CPU\ Time_A \times Clock\ Rate_A = 10s \times 2GHz = 20 \times 10^9$$

clock rate should be double

$$Clock\ Rate_B = \frac{Clock\ Cycles_B}{CPU\ Time_B} = \frac{1.2 \times Clock\ Cycles_A}{6s} = \frac{1.2 \times 20 \times 10^9}{6s} = 4GHz$$

Instruction Count and CPU

total num of instruction? actual num of instruction excuted

$$Clock\ Cycles = \ Instruction\ Count \times \text{CPI (Cycles Per Instruction)}$$

$$CPU\ Time = \ Instruction\ Count \times \text{CPI} \times Clock\ Cycle\ Time$$

$$= \frac{Instruction\ Count \times \text{CPI}}{Clock\ Rate}$$

1) total num of instructuon
2) average cycle
3) clock rate
이 세개가 결정한다. 실행 타임
instruction count cpi should be decreased

- ■ Instruction count for a program

  - Determined by program, ISA and compiler

risc는 cisc보다 적다?

- ■ Average cycles per instruction

  - Determined by CPU hardware 얼마나 많은 cycle이 일을 수행하기 위해 필요한지 for load etc

  - If different instructions have different CPU, average CPI affected by instruction mix

CPI Example

- Computer A: Cycle time = 250ps, CPI = 2.0
- Computer B: Cycle time = 500ps, CPI = 1.2
- Same ISA
- Which is faster, and by how much?

$$CPU\ Time_A = Instruction\ Count\ (IC) \times CPI_A \times Cycle\ Time_A$$

$$= IC \times 2.0 \times 250ps = IC \times 500ps$$

$$CPU\ Time_B = Instruction\ Count\ (IC) \times CPI_B \times Cycle\ Time_B$$

$$= IC \times 1.2 \times 500ps = IC \times 600ps$$

$$\frac{CPU\ Time_B}{CPU\ Time_A} = \frac{IC \times 600ps}{IC \times 500ps} = 1.2$$

A is faster than B by 1.2 times

CPI in More Detail

- If different instruction classes take different numbers of cycles

$$Clock\ Cycles = \sum_{i=1}^{n} (CPI_i \times Instruction\ Count_i)$$

- Weighted average CPI

$$CPI = \frac{Clock\ Cycles}{Instruction\ Count} = \sum_{i=1}^{n} \left(CPI_i \times \underbrace{\frac{Instruction\ Count_i}{Instruction\ Count}} \right)$$

Relative frequency

CPI Example

- Alternative compiled code sequences A and B

same program different instruction mips

Class	ALU	Load/Store	Branch
CPI for class	1	2	3
IC in sequence A	200	100	200
IC in sequence B	400	100	100

- Sequence A: IC = 500
  - Clock cycles
    = 200 x 1 + 100 x 2 + 200 x 3
    = 1000
  - Average CPI = 1000 / 500 = 2.0

- Sequence B: IC = 600
  - Clock cycles
    = 400 x 1 + 100 x 2 + 100 x 3
    = 900
  - Average CPI = 900 / 600 = 1.5

같은 **clock cycle then b is faster, they traded branch with alu**

C Sort Example (Revisited)

```
void swap(long long v[], long long k)
{
    long long temp;

    temp = v[k];
    v[k] = v[k+1];
    v[k+1] = temp;
}

void sort(long long v[], size_t n)
{
    size_t i, j;
    for (i = 1; i < n; i++)
        for (j = i - 1; j >= 0 && v[j] > v[j+1]; j--) {
            swap(v, j);
}
```

Effect of Compiler Optimization

- Compiled with gcc on Pentium 4 under Linux

Relative Performance
Instruction count

o3 get mor IC
but at the same tim
reducing CPI
depending on the///

Instruction count 뿐
아니라 CPi도 같이 봐이
우리가 성능 알 수 있다,

CC/IC = CPI

Clock Cycles

CPI
Effect of Language and Algorithm

■ Bubblesort Relative Performance
java byte code compiled to
without interpreting

algorithm에 따라서 밑에처럼 달라진다.
impriving 위해서

■ Quicksort Relative Performance

■ Quicksort vs. Bubblesort Speedup

Lessons

- Instruction count and CPI are not good performance indicators in isolation

- Compiler optimizations are sensitive to the algorithm

- Java/JIT compiled code is significantly faster than JVM interpreted
  - Comparable to optimized C in some cases

- Nothing can fix a dumb algorithm!

Iron Law of CPU Performance

이 슬라이드는 외워라.

$$CPU\ Time = \frac{Instructions}{Program} \times \frac{Cycles}{Instruction} \times \frac{Seconds}{Cycle}$$

$$= Instruction\ Count \times CPI \times Clock\ Cycle\ Time$$

	Instruction Count	CPI	Clock Cycle
Algorithm	○	△ micro 가 대부분	
Programming language	○	○	
Compiler	○	○	
ISA	○	○	○ risc라면 줄일 수
Microarchitecture	○ 테스트 java나 python사용하면 IC increase ISA - risc V cisc	○	○
Technology			○

Fallacy: MIPS as a Performance Metric

- **MIPS (Millions of Instructions Per Second) doesn't account for**

  - Differences in ISAs between computers

  - Differences in complexity between instructions

  one mips - one million
  two - two milion

  instruction count ignore so this is not good
  diffefent program different mips value
  not goot

  1) clock 2) IC 3) average cycle 세개 다중요

$$MIPS = \frac{Instruction\ count}{Execution\ time\ \times\ 10^6}$$

$$= \frac{Instruction\ count}{\dfrac{Instruction\ count\ \times CPI}{Clock\ rate}\ \times\ 10^6} = \frac{Clock\ rate}{CPI\ \times\ 10^6}$$

  - CPI varies between programs on a given CPU

Benchmarking

Chap. 1.9

Benchmarks

- **How to measure the performance?**
  - Performance best determined by running a real application
  - Use programs typical of expected workload

- **Small benchmarks**   **set of program that are used for performance**
  - Nice for architects and designers
  - Easy to standardize
  - Can be abused

SPEC CPU Benchmark

- **SPEC (Standard Performance Evaluation Corporation)**
  - A non-profit organization that aims to "produce, establish, maintain and endorse a standardized set" of performance benchmarks for computers
  - CPU, Power, HPC (High-Performance Computing), Web servers, Java, Storage, …
  - http://www.spec.org

- **SPEC CPU benchmark**
  - An industry-standardized, CPU-intensive benchmark suite, stressing a system's processor, memory subsystem and compiler
    - Companies have agreed on a set of real program and inputs
    - Valuable indicator of performance (and compiler technology)
  - CPU89 → CPU92 → CPU95 → CPU2000 → CPU2006 → CPU2017
  - Can still be abused   **input size 증가**

Benchmark Games

An embarrassed Intel Corp. acknowledged Friday that a bug in a software program known as a compiler had led the company to overstate the speed of its microprocessor chips on an industry benchmark by 10 percent. However, industry analysts said the coding error...was a sad commentary on a common industry practice of "cheating" on standardized performance tests...The error was pointed out to Intel two days ago by a competitor, Motorola ...came in a test known as SPECint92...Intel acknowledged that it had "optimized" its compiler to improve its test scores. The company had also said that it did not like the practice but felt to compelled to make the optimizations because its competitors were doing the same thing...At the heart of Intel's problem is the practice of "tuning" compiler programs to recognize certain computing problems in the test and then substituting special handwritten pieces of code...

SPEC CPU2006

- Elapsed time to execute a selection of programs
  - Negligible I/O, so focuses on CPU performance

- Normalize relative to reference machine
  - Sun's historical "Ultra Enterprise 2" introduced in 1997
  - 296MHz UltraSPARC II processor

- Summarize as geometric mean of performance ratios
  - CINT2006: 12 integer programs written in C and C++
  - CFP2006:   17 FP programs written in Fortran and C/C++

$$\sqrt[n]{\prod_{i=1}^{n} \text{Execution time ratio}_i}$$

SPEC CPU2006 Suites

Integer Benchmarks (CINT2006)			Floating Point Benchmarks (CFP2006)		
perlbench	C	Perl programming language	bwaves	Fortran	Fluid dynamics

SPEC Power Benchmark

- **SPECpower_ssj2008**
  - The first industry-standard SPEC benchmark for evaluating the power and performance characteristics of server class computers
  - Initially targets the performance of server-side Java
  - Power consumption of server at different workload levels (0% ~ 100%)
    - Performance: ssj_ops/sec
    - Power: Watts (Joules/sec)

$$Overall\ ssj\_ops\ per\ Watt = \left(\sum_{i=0}^{10} ssj\_ops_i \right) \Big/ \left(\sum_{i=0}^{10} power_i \right)$$

SPECpower_ssj2008 for Xeon X5650

Target Load %	Performance (ssj_ops)	Average Power (Watts)
100% whole time busy	865,618	258
90%	786,688	242
80%	698,051	224
70%	607,826	204
60%	521,391	185
50% 이상이면 reject	436,757 num of operations per seceond	170
40%	345,919	157
30%	262,071	146
20%	176,061	135
10%	86,784	121
0%	0	80
Overall Sum	4,787,166	1,922
Σssj_ops/Σpower =		2,490

이게 벤치마크 score higer should be better!!!!!!!!!!!!

Fallacy: Low Power at Idle

- **Look back at Xeon power benchmark**
  - At 100% load: 258W
  - At 50% load: 170W (66%)
  - At 10% load: 121W (47%)

- **Google data center**
  - Mostly operates at 10% - 50% load
  - At 100% load less than 1% of the time

- **Consider designing processors to make power proportional to load**
Summary

- Performance is specific to a particular program(s)
  - Total execution time is a consistent summary of the performance

- For a given architecture, performance increases come from
  - Increases in clock rate (without adverse CPI effects)
  - Improvements in processor organization that lower CPI
  - Compiler enhancements that lower CPI and/or instruction count
  - Algorithm/language choices that affect instruction count

- Pitfall: Expecting improvement in one aspect of a machine's performance to affect the total performance
